# welcome

---

Thank you for purchasing *React Native in Action*! With the growing demand for app development and the increasing complexity that app development entails, React Native comes along at a perfect time, making it possible for developers to build performant cross platform native apps much easier than ever before, all with a single programming language: JavaScript. This book gives any iOS, Android, or web developer the knowledge and confidence to begin building high quality iOS and Android apps using the React Native Framework right away.

When React Native was released in February of 2015, it immediately caught my attention, as well as the attention of the lead engineers at my company. At the time, we were at the beginning stages of developing a hybrid app using Cordova. After looking at React Native, we made the switch and bet on React Native as our existing and future app development framework. We have been very pleased at the ease and quality of development that the framework has allowed the developers at our company, and I hope that once you are finished reading this book, you will also have a good understanding of the benefits that React Native has to offer.

Since I began working with React Native at its release, it's been a pleasure to work with it and to be involved with its community. I've spent much time researching, debugging, blogging, reading, building things with, and speaking about React Native. In my book, I boil down what I have learned into a concise explanation of what React Native is, how it works, why I think it's great, and the important concepts needed to build high quality mobile apps in React Native.

Any developer serious about app development or wanting to stay ahead of the curve concerning emerging and disruptive technologies should take a serious look at React Native, as it has the potential to be the holy grail of cross-platform app development that many developers and companies have been hoping for.

—Nader Dabit

## **Preface**

I've always been fascinated with the idea of Mobile application development. The idea of building mobile apps is one of the reasons I wanted to learn how to code. This fascination has led me down many paths, from Objective-C to JQuery mobile to Cordova & now to React Native.

Because my career centered around writing JavaScript, I've also always been drawn to technologies that increased my efficiency by leveraging my existing skillset, allowing me to do more than just web development. Finding ways to be more efficient has been core to my career in general when choosing paths to follow and rabbit holes to dive into.

When React Native landed for the first time I knew that it was going to be something of significance. There were already thousands of React & JavaScript developers in the world. React Native gave these developers a way to extend their existing skillset into the world of mobile application development in a way that Cordova & other options did not, & also appealed heavily to React developers who were at the time the most rapidly growing segment of all front-end developers. The framework also delivered a substantial increase in quality of applications that could be build vs other options that were available in the similar space.

After writing my first application and shipping it to the app store, I had learned quite a bit and decided to start answering questions on Stack Overflow. I quickly began realizing that I had valuable knowledge that I could share & help the community as well as help my career, so I began hanging out there more and more answering questions.

While answering these questions I was learning a lot, and at some point, made a conscious decision to specialize 100% in the React Native framework. I had heard from many successful developers & consultants that their decision to specialize had helped them in their careers to be more productive, get more business, & demand a higher rate, so I decided to try out being a specialist for the first time in my career.

This decision turned out to be great for my career, & I quickly began getting leads for consulting & then later on, training.

I have seen the framework grow from its infancy to what it is today and have seen many developers & companies rapidly increase their efficiency and productivity by taking advantage of what the framework has to offer.

I think we're at an exciting time for React Native as we are seeing many Fortune 500 companies & enterprises pick it up over the past year, finally solidifying it as a first-class choice in their developer toolkit, giving more and more confidence to people considering betting their companies & applications on the framework.

It will be exciting to see how the framework evolves and to witness more and more apps that are shipped using React Native as time goes on!

## Acknowledgments

This is the first time I have ever written a book, and it has been a really good learning experience, and much more work than I had first anticipated. Over the time of writing this book, my career has changed a couple of times & my time obligations right along with it, giving me varying amounts of time to spend committed to the book.

First and foremost, Nickie Buckner & Marina Michaels are the reason that this book is complete. If it were not for them it would be in editing indefinitely, as I was unable to rewrite a couple of chapters in a reasonable amount of time & Nickie stepped in in a huge way to finish the book. Marina has also done more than what was called for in helping the last 20% of the way as my time has become more and more constrained.

My wife Lilly has been working overtime to help in my absence with her already exceedingly high normal duties as I have worked late nights at work & sometimes at home to write this book. My kids Victor & Eli because they are awesome & I love them so much. My parents for putting me in a position to be able to learn things & get second, third and fourth chances at life.

The React Native community, the React Native team (Jordan Walke, Christopher Chedeau, Adam Wolff & everyone at Facebook over the years that I did not mention). Monte Thakkar who took over React Native Elements open source while I wrote this (& all React Native Training open source contributors). Eric Vicenti & Brent Vatne & all of the people who have worked on Navigation and so many other projects. that I use from day to day. Charlie Cheever who has with Expo pushed the development of many React Native projects & by extension of Expo has helped many open source projects that many people use today. Parasharum N who has been committed to building things around React Native for years and now works on React Native at Facebook & has always been a great asset to the community & ecosystem. Peter Piekarczyk, Kevin Old, Lee Johnson, Gant Laborde, & Spencer Carli who have consistently helped with the React Native Radio podcast. Russ Davis & SchoolStatus for the opportunity to have learned React Native on the job which is how I initially got started with it in the first place. OrtaTherox & the people at Artsy for their commitment to the React Native community with their amazing blog & open source. Leland Richardson & Devin Abbott & all of the team at Airbnb who gave React Native a fair shot & contributed extensively to the ecosystem even though the framework did not work out for Airbnb in the long run. The Wix team who have contributed many amazing projects to the React Native open source ecosystem. Mike Grabowski & Anna Lankauf of Callstack for being in charge of releasing React Native open source, & for many contributions to the React Native open source ecosystem & for collaborating with me on things over the years. Jason Brown for pushing amazing blog posts & teaching me about animations early on.

I'm sure I left many people out, & if that person is you I apologize but thank you for your contribution as well.

## About this Book

React Native in action was written to get you up and running with the React Native framework as quickly and seamlessly as possible with a combination of real-world examples, discussions around APIs & development techniques, & a focus on learning things that will translate into real world scenarios.

We begin by having an overview of React Native in chapter 1, before going into an overview of how React works in chapter 2. From chapter 3 until the end of the book, we build a few applications containing functionality that you will use building your application in the real world & also deep dive on topics such as data architecture, navigation, & animations, giving you a well-rounded understanding of how to build mobile apps using React Native.

## About the Author

Nader Dabit is a Developer Advocate at AWS Mobile, where he is working on tools & services to allow developers to build full-stack web & mobile applications using their existing skillset. He is also the founder of React Native Training & the host of the React Native Radio podcast.

# *Part 1*

## *Getting started with React Native*

In chapter 1, we'll get you up and running with React Native by going over what React Native is, how it works, what its relationship with React is, and when you might want to use React Native (and when you might not). This chapter has an overview of React Native's components, which are at the core of React Native. It concludes with creating a small React Native project.

Chapter 2 covers state and props: what they are, how they work, and why they are important in React Native application development. It also covers the React Component specification and React lifecycle methods.

In chapter 3, you build your first React Native app, a Todo app, from the ground up, and you'll learn about using the developer menu in iOS and Android for, among other things, debugging your app.

# 1

## *Getting started with React Native*

### **This chapter covers**

- **Introducing React Native**
- **The strengths of React Native**
- **Creating components**
- **Creating a starter project**

Native mobile application development can be complex. With the complicated environments, verbose frameworks, and long compilation times developers face, developing a quality native mobile application is no easy task. It's no wonder that the market has seen its share of solutions come onto the scene that attempt to solve the problems that go along with native mobile application development and try to somehow make it easier.

At the core of this complexity is the obstacle of cross-platform development. The various platforms are fundamentally different and don't share much of the same development environments, APIs, or code. Because of this, you must have separate teams working on each platform, which is both expensive and inefficient.

This is an exciting time in mobile application development. We are witnessing a new paradigm in the mobile development landscape and React Native is on the forefront of this shift in how we build and engineer our mobile applications, as it is now possible to build native performing cross-platform apps as well as web applications with a single language and team. With the rise of mobile devices and the subsequent increase in demand of talent driving developer salaries higher and higher, React Native brings to the table the ability to deliver quality applications across all platforms at a fraction of the time and cost, while still delivering a high-quality user experience and a delightful developer experience.

## 1.1 Introducing React and React Native

React Native is a framework for building native mobile apps in JavaScript using the React JavaScript library and compiles to real native components. If you're not sure what React is, it is a JavaScript library open sourced by and used within Facebook. It was originally used to build user interfaces for web applications. It has since evolved and can now also be used to build server-side and mobile applications (using React Native).

React Native has a lot going for it. Besides being backed and open sourced by Facebook, it also has a tremendous community of motivated people behind it. Facebook groups, with its millions of users, is powered by React Native as well as Facebook Ads Manager. Airbnb, Bloomberg, Tesla, Instagram, Ticketmaster, Soundcloud, Uber, Walmart, Amazon, and Microsoft are also some of the companies either investing in or using React Native in production.

With React Native, developers can build native views and access native platform-specific components using JavaScript. This sets React Native apart from other hybrid app frameworks like Cordova and Ionic, which package web views built using HTML and CSS into a native application. Instead, React Native takes JavaScript and compiles it into a true native application that can leverage platform specific APIs and components. Other alternatives like Xamarin take the same approach, but Xamarin apps are built using C# not JavaScript. Many web developers will already have JavaScript experience, which helps ease the transition from web to mobile app development.

There are many benefits to choosing React Native as a mobile application framework. Because the application renders native components and APIs directly, the speed and performance are much better than hybrid frameworks such as Cordova or Ionic. With React Native we are writing our entire application using a single programming language, JavaScript. That way, you can reuse a lot of code, therefore reducing the time it takes to get a cross-platform application shipped. Hiring and finding quality JavaScript developers is much easier and cheaper than hiring Java or Objective C / Swift developers, leading to an overall less expensive process.

React Native applications are built using JavaScript and JSX. JSX is something we will be discussing in depth in this book, but for now think of it as a JavaScript syntax extension that looks like html or xml.

We will dive much deeper into React in Chapter 2, but until then, let's touch on a few core concepts as an introduction.

### 1.1.1 A basic React class

Components are the building blocks of a React or React Native application. The entry point of your application is a component that requires and is made of other components. These components may also require other components and so on and so forth.

There are two main types of React Native components, stateful and stateless.

### Listing 1.1 Stateful component using ES6 class

```
class HelloWorld extends React.Component {
  constructor() {
    super()
    this.state = { name: 'Chris' }
  }

  render () {
    return (
      <SomeComponent />
    )
  }
}
```

### Listing 1.2 Stateless component

```
const HelloWorld = () => (
  <SomeComponent />
)
```

The main difference is that the stateless components do not hook into any lifecycle methods and hold no state of their own, so any data to be rendered must be received as props. We will go through the lifecycle methods in depth in Chapter 2, but for now let's take a look at a class and take a first look at them (listing 1.3).

### Listing 1.3 Creating a basic React Native class

```
import React from 'react'
import { View, Text, StyleSheet } from 'react-native'

class HelloWorld extends React.Component {
  constructor () { // A
    super()
    this.state = {
      name: 'React Native in Action'
    }
  }
  componentDidMount () { // C
    console.log('mounted..')
  }
  render () { // B
    return (
      <View style={styles.container}>
        <Text>{this.state.name}</Text>
      </View>
    )
  }
}

const styles = StyleSheet.create({
  container: {
    marginTop: 100,
    flex: 1
  }
})
```

**MOUNTING** Something to keep in mind when we discuss the following methods is the concept of mounting. When a component is created, the React component lifecycle is instantiated, triggering the methods we used above and will discuss below.

At the top of the file, we require `React` from `'react'`, as well as `View`, `Text`, and `StyleSheet` from `'react-native'`. `View` is the most fundamental build block for building React Native components and the UI in general and can be thought of like a `div` in HTML. `Text` allows us to create text elements and is comparable to a `span` tag in HTML. `StyleSheet` allows us to create style objects to use in our application. These two packages (`react` and `react-native`) are available as npm modules.

When the component first loads, we set a state object with the property `name` in the constructor **(A)**. For data in a React Native application to be dynamic, it either needs to be set in the state or passed down as props. Here, we have set the state in the constructor and can therefore change it if we would like by calling:

```
this.setState({
  name: 'Some Other Name'
})
```

which would re-render the component. Setting the variable in state, allows us to update the value elsewhere in the component.

`render` is then called **(B)**, which examines props and state and then must return either a single React Native element, `null`, or `false`. This means that if you have multiple child elements, they must be wrapped in a parent element. Here the components, styles, and data are combined to create what will be rendered to the UI.

The final method in the lifecycle is `componentDidMount` **(C)**. If you need to do any API calls or ajax requests to reset the state, this is usually the best place to do so.

Finally, the UI is rendered to the device and we can see our result.

### 1.1.2 React lifecycle

When a React Native Class is created, there are methods that are instantiated that we can hook into. These methods are called lifecycle methods, and we will cover them in depth in chapter 2. The methods we saw in figure 1.1 were `constructor`, `componentDidMount`, and `render`, but there are a few more and they all have their own use cases.

Lifecycle methods happen in sync and help manage the state of components as well as execute code at each step of the way if we would like. The only lifecycle method that is required is the `render` method, all the others are optional.

When working with React Native, we are fundamentally working with the same lifecycle methods and specifications as one would use when using React.

## 1.2 What you will learn

In this book, we will cover everything you will need to know to build robust mobile applications for iOS and Android using the React Native framework.

Because React Native is built using the React library, we will begin by covering and thoroughly explaining how React works in Chapter 2.

We will then cover styling, touching on most of the styling properties available in the framework. Because React Native uses flexbox for laying out the UI, we will dive deep into how flexbox works and discuss all the flexbox properties. If you've used flexbox in CSS for layout on the web, all of this will be very familiar to you, but keep in mind that the flexbox implementation used by React Native is not 100% the same.

We will then go through many of the native components that come with the framework out of the box and walk through how each of them works. In React Native, a component is basically a chunk of code that provides a specific functionality or UI element and can easily be used in the application. Components will be covered extensively throughout this book as they are the building blocks of a React Native application.

There are many ways to implement navigation, each with their nuances, pros and cons. We will discuss navigation in depth and cover how to build robust navigation using the most important of the navigation APIs. We will be covering not only the native navigation APIs that come out of the box with React Native, but also a couple of community projects available through npm.

After learning navigation, we will then cover both cross platform and platform specific APIs available in React Native and discuss how they work in depth.

It will then be time for us to start working data using network requests, asyncstorage (a form of local storage), firebase, and websockets.

Then we will dive into the different data architectures and how each of them works to handle the state of our application.

Finally, we will look at testing and a few different ways to do so in React Native.

## **1.3 What you should know**

To get the most out of this book, you should have a beginner to intermediate knowledge of JavaScript. Much of our work will be done with the command line, so a basic understanding of how to use the command line is also needed. You should also understand what npm is and how it works on at least a fundamental level. If you will be building in iOS, a basic understanding of Xcode is beneficial and will speed things along but is not necessary. Similarly, if you're building for Android, a basic understanding of Android Studio will also be beneficial but not necessary.

Fundamental knowledge of newer JavaScript features implemented in the ES2015 release the JavaScript programming language is beneficial but not necessary. Some conceptual knowledge on MVC frameworks and Single Page Architecture is also good but not necessary.

## **1.4 Understanding how React Native works**

Let's take a look at how React Native works by learning about JSX, the threading model, React, unidirectional data flow, & more.

### **1.4.1 JSX**

React and React native both encourage the use of JSX. JSX is basically is a syntax extension to JavaScript that looks similar to XML. You can build React Native components without JSX, but JSX makes React and React Native a lot more readable and easier to maintain. JSX may seem strange at first, but it is extremely powerful, and most people grow to love it.

### **1.4.2 Threading**

All JavaScript operations, when interacting with the native platform, are done in a separate thread, allowing the user interface as well as any animations to perform smoothly. This thread is where the React application lives, and all API calls, touch events, and interactions are processed. When there is a change to a native-backed component, updates are batched and sent to the native side. This happens at the end of each iteration of the event-loop. For most React Native applications, the business logic runs on the JavaScript thread.

### **1.4.3 React**

A great feature of React Native is that it uses React. React is an open-source JavaScript library that is also backed by Facebook. It was originally designed to build applications and solve problems on the web. This framework has become extremely popular and used since its release, with many established companies taking advantage of its quick rendering, maintainability, and declarative UI among other things. Traditional DOM manipulation is very slow and expensive in terms of performance and should be minimized. React bypasses the traditional DOM with something called the 'Virtual DOM'. The Virtual DOM is basically a copy of the actual DOM in memory, and only changes when comparing new versions of the Virtual Dom to old versions of the Virtual DOM. This allows the minimum number of DOM operations needed to achieve the new state.

### **1.4.4 Unidirectional data flow**

React and React Native emphasize unidirectional, or one-way, data flow. Because of how React Native applications are build, this one-way data flow is easy to achieve.

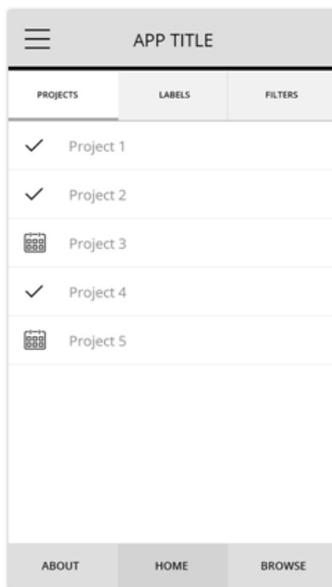

### **1.4.5 Diffing**

React takes this idea of diffing and applies it to native components. It takes your UI and sends the smallest amount of data to the main thread to render it with native components. Your UI is declaratively rendered based on the state and React uses diffing to send the necessary changes over the bridge.

### **1.4.6 Thinking in components**

When building your UI in React Native, it is useful to think of your application being as composed of a collection of components, and then build your UI. If you think about how a page is set up, we already do this conceptually, but instead of component names, we normally use concepts, names or class names like header, footer, body, sidebar, and so on. With React

Native, we can give these components actual names that make sense to us and other developers who may be using our code, making it easy to bring new people into a project, or hand a project off to someone else. Let's look at an example mockup that our designer has handed us. We will then think of how we can conceptualize this into components.

**Figure 1.1** Final example app design / structure

The first thing to do is to mentally break the UI elements up into what they represent. So, in the above mockup, we have a header bar, and within the header bar we have a title and a menu button. Below the header we have a tab bar, and within the tab bar we have three individual tabs. Go through the rest of the mockup and think of what the rest of the items might be as well. These items that we are identifying will be translated into components. This is the way you should think about composing your UI. When working with React Native, you should break down common elements in your UI into reusable components and define their interface accordingly. When you need this element any time in the future, it will be available for you to reuse.

Breaking up your UI elements in to reusable components is not only good for code reuse but will also make your code very declarative and understandable. For instance, instead of twelve lines of code implementing a footer, the element could simply be called footer. When looking at code that is built in this way, it is much easier to reason about and know exactly what is going on.

Let's look at how the design in Figure 1.1 could be broken up in the way we just described:

**Figure 1.2** App structure broken down into separate components

The names I have used here could be whatever makes sense to you. Look at how these items are broken up and some of them are grouped together. We have logically separated these items into individual and grouped conceptual components. Next, let's see how this would look using actual React Native code.

First, let's look at how the main UI elements would look on our page:

```
<Header />
<TabBar />
<ProjectList />
<Footer />
```

Next, let's see how our child elements would look:

TabBar:

```
<TabBarItem />
<TabBarItem />
<TabBarItem />
```

ProjectList:

```
// Add a Project component for each project in the list:
<Project />
```

As you can see, we have used the same names that we declared in figure 1.2, though they could be whatever makes sense to you.

## **1.5 Acknowledging React Native's strengths**

As discussed earlier, one of the main strengths React Native has going for it is that it uses React. React, like React Native, is an open source project that is backed by Facebook. As of the time of this writing, React has over 100,000 stars and more than 1,100 contributors on Github, which shows that there is a lot of interest and community involvement in the project, making it easier to bet on as a developer or as a project manager. Because React is developed and maintained and used by Facebook, it has some of the most talented engineers in the world overseeing it, pushing it forward and adding new features, and it will probably not be going away anytime soon.

### **1.5.1 Developer availability**

With the rising cost and falling availability of native mobile developers, React Native enters the market with a key advantage over native development: it leverages the wealth of existing talented web and JavaScript developers and gives them another platform in which to build without having to learn a new language.

### **1.5.2 Developer productivity**

Traditionally, to build a cross platform mobile application, you needed both an Android team as well as an iOS team. React Native allows you to build your Android, iOS, and soon Windows applications using only a single programming language, JavaScript, and possibly even a single team, dramatically decreasing development time and development cost, while increasing productivity. As a native developer, the great thing about coming to a platform like this is the fact that you are no longer tied down to being only an Android or iOS developer, opening the door for a lot of opportunity. This is great news for JavaScript developers as well, allowing them to spend all of their time in one state of mind when switching between web and mobile projects. It is also a win for teams who were traditionally split between Android and iOS, as they can now work together on a single codebase.

To underscore these points, you can also share your data architecture not only cross platform, but also on the web, if you are using something like Redux, which we will look at in a later chapter.

### **1.5.3 Performance**

If you follow other cross platform solutions, you are probably aware of solutions such as PhoneGap, Cordova, and Ionic. While these are also viable solutions, the consensus is that the performance has not yet caught up to the experience a native app delivers. This is where React Native also shines, as the performance is usually unnoticeable from that of a native mobile app built using Objective-C/Swift or Java.

### **1.5.4 One-way data flow**

One-way data flow separates React and React Native from not only most other JavaScript frameworks, but also any MVC framework. React differs in that it incorporates a one-way data

flow, from top-level components all the way down. This makes applications much easier to reason about, as there is one source of truth for your data layer as opposed to having it scattered about your application. We will look at this in more detail later in the book.

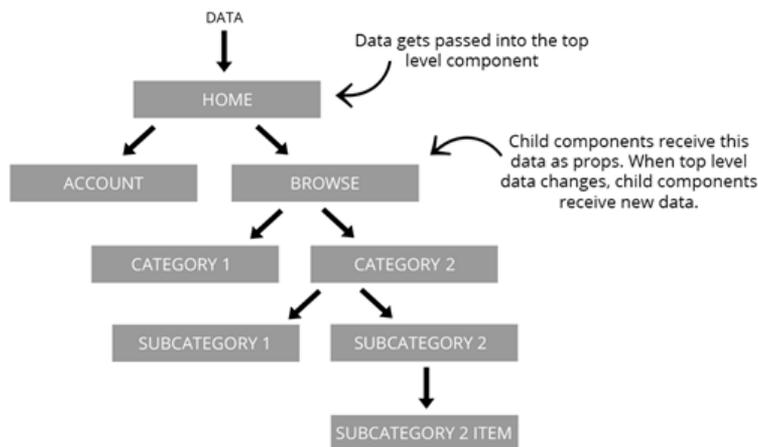

Figure 1.3 How one-way data flow works

### 1.5.5 Developer experience

The developer experience is a major win for React Native. If you've ever developed for the web, you're aware of the snappy reload times of the browser. Web development has no compilation step, just refresh the screen and your changes are there. This is a far cry from the long compile times of native development. One of the reasons Facebook decided to develop React Native was to overcome the lengthy compile times of the Facebook application when using native iOS and Android build tools. Even if they needed to make a small UI change, or any change, they would have to wait a long time while the program compiled to see the results. This long compilation time results in decreased productivity and increased developer cost. React Native solves this issue by giving you the quick reload times of the web, as well as Chrome and Safari debugging tools, making the debugging experience feel a lot like the web.

React Native also has something called Hot Reloading built in. What does this mean? Well, while developing an application, imagine having to click a few times into your app to get to the place in your app that you are developing for. While using Hot Reloading, when you make a code change, you do not have to reload and click back through the app to get to the current state. While using this feature in React Native, you simply save the file and the application reloads only the component which you have made changes to, instantly giving you feedback and updating the current state of the ui without having to click back through the app to get to the state you are working in.

### **1.5.6 Transpilation**

Transpilation is typically when something known as a transpiler takes source code written in one programming language and produces the equivalent code in another language. With the rise of new ECMAScript features and standards, transpilation has spilled over to also include taking newer versions and yet to be implemented features of certain languages, in our case JavaScript, and producing compiled standard JavaScript, making the code usable by platforms that can only process older versions of the language.

React Native uses Babel to do this transpilation step, and it is built in by default. Babel is an open source tool that transpiles the most bleeding edge JavaScript language features in to code that can be used today. This means that we do not have to wait for the bureaucratic process of language features being proposed, approved, and then implemented before we can use them. We can start using it as soon as the feature makes it into Babel, which is usually very quickly. JavaScript classes, arrow functions and object destructuring are all examples of powerful ES2015 features that have not made it into all browsers and runtimes yet, but with Babel and React Native, you can use them all today with no worries about whether they will work. If you like this, it is also available on the web.

### **1.5.7 Productivity and efficiency**

Native mobile development is becoming more and more expensive, and because of this, engineers who can deliver applications across platforms and stacks will become extremely valuable and in demand. Once React Native, or something like it if it comes along, makes developing desktop and web as well as mobile applications using a single framework mainstream, there will be a restructuring and rethinking of how engineering teams are organized. Instead of a developer being specialized in a certain platform, such as iOS or web, they will oversee features across platforms. In this new era of cross platform and cross stack engineering teams, developers delivering native mobile, web, and desktop applications will be more productive and efficient and will therefore be able to demand a higher wage than a traditional web developer only able to deliver web applications.

Companies that are hiring developers for mobile development stand to benefit the most out of using React Native. Having everything written in one language makes hiring a lot easier and less expensive. Productivity also soars when your team is all on the same page, working within a single technology, which makes collaboration and knowledge sharing easier.

### **1.5.8 Community**

The React community, and by extension the React Native community, is one of the most open and helpful groups I have ever interacted with. When running into issues that I have not been able to resolve on my own, by searching online or Stack Overflow, I have reached out directly to either a team member or someone in the community and have had nothing but positive feedback and help.

### **1.5.9 Open source**

React Native is open source. This offers a wealth of benefits. First, in addition to the Facebook team there are hundreds of developers that contribute to React Native. If there are bugs, they are pointed out much faster than proprietary software, which will only have the employees on that specific team working on bug fixes and improvements. Open source usually gets closer to what users want because the users themselves can have a hand in making the software what they want it to be. Between the cost of purchasing proprietary software, licensing fees, and support costs, open source also wins when measuring price.

### **1.5.10 Immediate updates**

Traditionally when publishing new versions of an app, you are at the mercy of the app store approval process and schedule. This is a long a tedious process and can take up to two weeks. When you have a change, even if it is something extremely small, it is a painful process to release a new version of your application. React Native, as well as hybrid application frameworks, allow you to deploy mobile app updates directly to the user's device, without going through an app store approval process. If you are used to the web, and the rapid release cycle it must offer, you can now also do this with React Native and other hybrid application frameworks.

### **1.5.11 Other solutions for building cross-platform mobile applications**

React Native is not the only option when building a cross-platform mobile application. There are multiple other options available, with the main ones being Cordova, Xamarin, and Flutter.

Cordova is basically just a native shell around a web application that allows the developer to access native APIs within the application. Unlike traditional web applications, Cordova apps can be deployed to the App Store & Google Play Store. The benefits of using something like Cordova is that there is not much more to learn if you are already a web developer as you can use html, JavaScript, CSS, and your JavaScript framework of choice. The main drawback of Cordova is that you will have a hard time matching the performance and smooth UI that React Native offers since you are still relying on the DOM since you are still working with mainly web technologies.

Xamarin is a framework that allows developers to build iOS, Android, Windows & Mac OS applications using a single codebase written in C#. Xamarin compiles to a native app in different ways depending on the platform that is being targeted. Xamarin has a free tier that allows developers to build and deploy mobile applications and a paid tier for larger or enterprise companies. Xamarin will probably appeal more to native developers since it does not have similarities to web technologies like React Native & Cordova.

Flutter is a framework open sourced by Google that uses the Dart programming language to build applications that run on iOS & Android platforms.

## 1.6 React Native's drawbacks

Now that we've gone over the benefits of using React Native, let's look at a few reasons and circumstances where you may not want to choose the framework.

First, React Native is still immature when compared to other platforms such as native iOS and Android, as well as Cordova. The feature parity is not there yet with either native or Cordova. While most functionality is now built in, there may be times where you need some functionality that is not yet available, and this means you will either must dig into the native code to build it yourself, hire someone to do it, or not implement the feature at all.

Another thing to think about is the fact that you and or your team must learn a completely new technology if you are not already familiar with React. While most people seem to agree that React is easy to pick up, if you are already proficient with Angular and Ionic for example and you have an application deadline coming up, it may be wise to go with what you already know instead of spending the time it takes to learn and train your team on a new tech.

In addition to learning React and React Native, you must also become familiar with Xcode and the Android development environments, which can take some getting used to as well.

Finally, React Native is an abstraction built on top of existing platform APIs. This means that when newer versions of iOS, Android, or other future platforms are released, there may be a time when React Native will be behind on the new features released with the newer version of the other platforms, forcing you to have to either build custom implementations to interact with these new APIs or wait until React Native regains feature parity with the new release.

## 1.7 Creating and using basic components

Components are the fundamental building blocks in React Native, and they can vary in functionality and type. Examples of components in popular use cases could be a button, header, footer, or navigation component. They can vary in type from an entire View, complete with its own state and functionality, all the way to a single stateless component that receives all its props (properties) from its parent.

### 1.7.1 An overview of components

At the core of React Native is the concept of components. React Native has built in components that are described as Native components in the book, but you will also build custom components using the framework. Components are a collection of data and UI elements that make up your views and ultimately your application. We will go in depth on how to build, create and use components in this book.

As we mentioned earlier, React Native components are built using JSX. Let's run through a couple of basic examples of what JSX in React Native looks like vs HTML:

**Table 1.1 JSX components vs HTML elements**

### 1. Text component

HTML	React Native JSX
<code>&lt;span&gt;Hello World&lt;/span&gt;</code>	<code>&lt;Text&gt;Hello World&lt;/Text&gt;</code>

### 2. View component

HTML	React Native JSX
<code>&lt;div&gt;</code> <code>  &lt;span&gt;Hello World 2&lt;/span&gt;</code> <code>&lt;/div&gt;</code>	<code>&lt;View&gt;</code> <code>  &lt;Text&gt;Hello World 2&lt;/Text&gt;</code> <code>&lt;/View&gt;</code>

### 3. Touchable highlight component

HTML	React Native JSX
<code>&lt;button&gt;</code> <code>  &lt;span&gt;Hello World 2&lt;/span&gt;</code> <code>&lt;/button &gt;</code>	<code>&lt;TouchableHighlight&gt;</code> <code>  &lt;Text&gt;Hello World 2&lt;/Text&gt;</code> <code>&lt;/TouchableHighlight&gt;</code>

As you can see in table 1.1, JSX looks very similar to HTML or XML.

## 1.7.2 Native components

The framework offers native components out of the box, such as View, Text, and Image, among others. We will create our own components using these Native components as building blocks. For example, we may use the following markup to create our own Button component using React Native TouchableHighlight, and Text components (listing 1.4).

### Listing 1.4 Creating button component

```
import { Text, TouchableHighlight } from 'react-native'
const Button = () => (
  <TouchableHighlight>
    <Text>Hello World</Text>
  </TouchableHighlight>
)
export default Button
```

We can then import and use our new button like this (listing 1.5).

## Listing 1.5 Importing and using Button component

```
import React from 'react'
import { Text, View } from 'react-native'
import Button from './components/Button'
const Home = () => (
  <View>
    <Text>Welcome to the Hello World Button!</Text>
    <Button />
  </View>
)
```

Next, we will go through the fundamentals of what a component is, how they fit into the workflow, as well as common use cases and design patterns for building them.

### 1.7.3 Component composition

While components are usually composed using JSX, they can also be composed using JavaScript.

Below, we will be creating a component in several different ways so we can go over all the options when creating components.

We'll be creating this component:

```
<MyComponent />
```

This component simply outputs 'Hello World' to the screen. Now, let's look at how we can build this basic component. The only out of the box components we will be using to build this custom component are the View and Text elements we discussed earlier. Remember, a <View> component is similar to an html <div>, and a <Text> component is similar to an html <span>.

Let's look at a few ways that you can create a component. The entire application does not have to be consistent in its component definitions, but it is usually recommended that you do try to stay mostly consistent with either one or the other.

#### 1. CREATECLASS SYNTAX (ES5, JSX)

This is the way to create a React Native component using ES5 syntax. While you will probably still see this syntax in use in some older documentation and examples, this syntax is not being used in newer documentation and is now deprecated. Because of this, we will be focusing on the ES2015 class syntax for the rest of the book but will review the `createClass` syntax here just in case you come across it in some older code.

```
const React = require('react')
const ReactNative = require('react-native')
const { View, Text } = ReactNative

const MyComponent = React.createClass({
  render() {
    return (
      <View>
        <Text>Hello World</Text>
      </View>)
  }
})
```

```
})
```

## 2. CLASS SYNTAX (ES2015, JSX)

The main way to create stateful React Native components is using ES2015 classes. This is the way we will be creating our *stateful* components for the rest of the book and is now the recommended way to do so by the community and creators of React Native.

```
import React from 'react'
import { View, Text } from 'react-native'

class MyComponent extends React.Component {
  render() {
    return (
      <View>
        <Text>Hello World</Text>
      </View>)
  }
}
```

## 3. STATELESS (REUSABLE) COMPONENT (JSX)

Since the release of React 0.14, we have had the ability to create what are called stateless components. We have not yet dived into state, but just remember that stateless components are basically pure functions that cannot mutate their own data, and do not contain their own state. This syntax is much cleaner than the `class` or `createClass` syntax.

```
import React from 'react'
import { View, Text } from 'react-native'

const MyComponent = () => (
  <View>
    <Text>Hello World</Text>
  </View>
)

or

import React from 'react'
import { View, Text } from 'react-native'

function MyComponent () {
  return <View><Text>HELLO FROM STATELESS</Text></View>
}
```

## 4. CREELEMENT (JAVASCRIPT)

`React.createElement` is rarely used, and you will probably never need to create a React Native element using this syntax but may come in handy if you ever need more control over how you are creating your component, or if you are reading someone else's code. It will also give you a look at how JavaScript compiles JSX.

`React.createElement` takes a few arguments:

```
React.createElement(type, props, children) {}
```

Let's walk through these arguments:

- **type**: The element you want to render
- **props**: any properties you want the component to have
- **children**: child components or text

As you can see below, we pass in a View as the first argument to the first instance of React.createElement, an empty object as the second argument, and another element as the last argument.

In the second instance, we pass in Text as the first argument, an empty object as the second argument, and "Hello" as the final argument.

```
class MyComponent extends React.Component {
  render() {
    return (
      React.createElement(View, {},
        React.createElement(Text, {}, "Hello")
      )
    )
  }
}
```

Which is the same as declaring the component like this:

```
class MyComponent extends React.Component {
  render () {
    return (
      <View>
        <Text>Hello</Text>
      </View>
    )
  }
}
```

## 1.7.4 Exportable components

Next, let's look at another more in-depth implementation of a React Native component. Let's create an entire component that we can export and use in another file. We will walk through each piece of this code:

```
import React, { Component } from 'react'
import {
  Text,
  View
} from 'react-native'

class Home extends Component {
  render() {
    return (
      <View>
        <Text>Hello from Home</Text>
      </View>)
    )
  }
}

export default Home
```

Let's go over all the different pieces that make up the above component and discuss what's going on.

## **IMPORTING**

The following code imports React Native variable declarations:

```
import React, { Component } from 'react'
import {
  Text,
  View
} from 'react-native'
```

Here, we are importing React directly from the React library using a default import and importing Component from the React library using a named import. We are also using named imports to pull Text and View into our file.

The import statement using ES5 would look like this:

```
var React = require('react')
```

The above statement without using named imports would look like this:

```
import React = from 'react'
const Component = React.Component
import ReactNative from 'react-native'
const Text = ReactNative.Text
const View = ReactNative.View
```

The import statement is used to import functions, objects, or variables that have been exported from another module, file, or script.

## **COMPONENT DECLARATION**

The following code declares the component:

```
class Home extends Component { }
```

Here we are creating a new instance of a React Native Component class by extending it and naming it Home. As you can see, before we declared React.Component, we are now just declaring Component. This is because we have imported the Component element in the object destructuring statement, giving us access to Component as opposed to having to call React.Component.

## **THE RENDER METHOD**

Next, look at the Render method:

```
render() {
  return (
    <View>
      <Text>Hello from Home</Text>
    </View>)
}
```

The code for the component gets executed in the render method, and the content after the return statement returns what is rendered on the screen. When the render method is called, it should return a single child element. Any variables or functions declared outside of the render function can be executed here. If you need to do any calculations, declare any variables using state or props, or run any functions that do not manipulate the state of the component, you can do so here in between the `render()` method and the return statement.

## EXPORTS

Here, we export the component to be used elsewhere in our application. If you want to use the component in the same file, you do not need to export it. After it is declared, you can use it in your file, or export it to be used in another file. You may also use `module.exports = 'Home'` which would be ES5 syntax.

```
export default Home
```

### 1.7.5 Combining components

Let's look at how we might combine components. First, let's create a Home, Header and Footer component. In a single file, let's start by creating the Home Component:

```
import React, { Component } from 'react'
import {
  Text,
  View
} from 'react-native'

class Home extends Component {
  render() {
    return (
      <View>

      </View>
    )
  }
}
```

In the same file, below the Home class declaration, let's start by building out a Header component:

```
class Header extends Component {
  render() {
    return <View>
      <Text>HEADER</Text>
    </View>
  }
}
```

This looks nice, but let's rewrite the Header into a stateless component. We will discuss when and why it is good to use a stateless component versus a regular React Native class in depth later in the book. As you will begin to see, the syntax and code is much cleaner when we use stateless components:

```
const Header = () => (
```

```
<View>
  <Text>HEADER</Text>
</View>
)
```

Now, let's insert our Header into our Home component:

```
class Home extends Component {
  render() {
    return (
      <View>
        <Header />
      </View>
    )
  }
}
```

We'll then create a Footer and a Main view as well:

```
const Footer = () => (
  <View>
    <Text>Footer</Text>
  </View>
)

const Main = () => (
  <View>
    <Text> Main </Text>
  </View>
)
```

Now, we'll just drop those into our application:

```
class Home extends Component {
  render() {
    return (
      <View>
        <Header />
        <Main />
        <Footer />
      </View>
    )
  }
}
```

As you can see, the code we just wrote is extremely declarative, meaning it's written in such a way that it describes what you want to do, and is easy to understand in isolation.

This is a very high-level overview of how we will be creating our components and views in React Native but should give you a very good idea of how the basics work.

## 1.8 Creating a starter project

Now that we have gone over a lot of basic details about React Native, let's start digging into some more code. While we will be focusing on building apps using the React Native CLI, you can also use the Create React Native App CLI to create a new project.

### 1.8.1 Create React Native App CLI

You can create React Native project using the Create React Native App CLI, a project generator that is maintained in the React Community GitHub repository, mainly by the Expo team. Expo created Create React Native App project as a way to allow developers to get up and running with React Native without having to worry about installing all of the native SDKs that are involved with running a React Native project using the CLI.

To create a new project using Create React Native App, first install the CLI:

```
npm install -g create-react-native-app
```

To create a new project using the app using the CLI:

```
create-react-native-app myProject
```

### 1.8.2 React Native CLI

Before we go any further, make sure you see the appendix to verify that you have the necessary tools installed on your machine. If you do not have the required SDKs installed, you will not be able to continue building your first project using the React Native CLI.

To get started with the React Native starter project and the React Native CLI, open your command line and then create and navigate to an empty directory. Once you are there, install the react-native cli globally by typing the following:

```
npm install -g react-native-cli
```

After React Native is installed on your machine, you can initialize a new project by typing `react-native init` followed by the project name:

```
react-native init myProject
```

`myProject` can be any name that you choose.

The CLI will then spin up a new project in whatever directory you are in. Once this has finished, open the project in a text editor.

First, let's look at the main files and folders this has generated for us:

- `android` – This folder contains all the Android platform-specific code and dependencies. You won't need to go into this folder unless you are either implementing a custom bridge into Android, or if you install a plugin that calls for some type of deep configuration
- `ios` - This folder contains all the iOS platform-specific code and dependencies. You won't need to go into this folder unless you are either implementing a custom bridge into iOS or if you install a plugin that calls for some type of deep configuration
- `node_modules` – React Native uses something called npm (node package manager) to manage dependencies. These dependencies are identified and versioned in the `.package.json` file, and stored in the `node_modules` folder. When you install any new packages from the npm / node ecosystem, they will go in here. These can be installed using either npm or yarn.

- `.flowconfig` – Flow (also open sourced by Facebook) offers type checking for JavaScript. Flow is like Typescript, if you are familiar with that. This file is the configuration for flow, if you choose to use it.
- `.gitignore` – This is the place to store any file paths that you do not want in version control
- `.watchmanconfig` – Watchman is a file watcher that React Native uses to watch files and record when they change. This is the configuration for Watchman. No changes to this will be needed except for rare use cases.
- `index.js`- This is the entry point of the application. In this file, `App.js` is imported and `AppRegistry.registerComponent` is called, initializing the app.
- `App.js`- This is the default main import used in `index.js` containing the base project. This can be changed by deleting this file and replacing the main import in `index.js`.
- `package.json`- This file holds all of our npm configuration. When we npm install files, we can save them here as dependencies. We can also set up scripts to run different tasks.

Now, let's take a look at `App.js`

#### Listing 1.6 `App.js`

```
/**
 * Sample React Native App
 * https://github.com/facebook/react-native
 * @flow
 */

import React, { Component } from 'react';
import {
  Platform,
  StyleSheet,
  Text,
  View
} from 'react-native';

const instructions = Platform.select({
  ios: 'Press Cmd+R to reload,\n' +
    'Cmd+D or shake for dev menu',
  android: 'Double tap R on your keyboard to reload,\n' +
    'Shake or press menu button for dev menu',
});

export default class App extends Component<{}> {
  render() {
    return (
      <View style={styles.container}>
        <Text style={styles.welcome}>
          Welcome to React Native!
        </Text>
        <Text style={styles.instructions}>
          To get started, edit App.js
        </Text>
        <Text style={styles.instructions}>
          {instructions}
        </Text>
      </View>
    );
  }
}
```

```

        </Text>
      </View>
    );
  }
}

const styles = StyleSheet.create({
  container: {
    flex: 1,
    justifyContent: 'center',
    alignItems: 'center',
    backgroundColor: '#F5FCFF',
  },
  welcome: {
    fontSize: 20,
    textAlign: 'center',
    margin: 10,
  },
  instructions: {
    textAlign: 'center',
    color: '#333333',
    marginBottom: 5,
  },
});

```

As you can see, the above code looks very like what we went over in the last section. There are a couple of new items we have not yet seen:

StyleSheet  
Platform

Platform is an API that allows us to detect the current type operating system we are running on. This will allow us to check things like web, iOS, or Android.

StyleSheet is an abstraction like CSS stylesheets. In React Native you can declare styles either inline or using Stylesheets. As you can see in the first view, there is a container style declared:

```
<View style={styles.container}>
```

This corresponds directly to:

```

container: {
  flex: 1,
  justifyContent: 'center',
  alignItems: 'center',
  backgroundColor: '#F5FCFF',
}

```

At the bottom of the `index.js` file, you see

```
AppRegistry.registerComponent('book', () => book);
```

This is the JavaScript entry point to running all React Native apps. In the `index` file is the only place you will be calling this function. The root component of the app should register itself

with `AppRegistry.registerComponent()`. The native system can then load the bundle for the app and then actually run the app when it is ready.

Now that we have gone over what is in the file, let's run the project in either our iOS simulator or our Android emulator.

**Figure 1.4** React Native starter project – what you should see after running the starter project on the emulator.

In the Text element that contains 'Welcome to React Native', replace that with 'Welcome to Hello World!' or some text of your choice. Refresh the screen. You should see your changes.

## 1.9 Summary

- React Native is a framework for building native mobile apps in JavaScript using the React JavaScript library.
- Some of React Native's strengths are its performance, developer experience, ability to build cross platform with a single language, one-way data flow, and community. You may consider React Native over hybrid mainly because of its performance, and over Native mainly because of the developer experience and cross platform ability with a single language.
- JSX is a preprocessor step that adds an XML like syntax to JavaScript. You can use JSX to create a UI in React Native.
- Components are the fundamental building blocks in React Native. They can vary in functionality and type. You can create custom components to implement common design elements.

- Components that need state or lifecycle methods need to be created using a JavaScript class by extending the `React.Component` class.
- Stateless components can be created with less boilerplate for components that do not need to keep up with their own state.
- Larger components can be created by combining smaller subcomponents together.
